## Samenvatting

Vergelingsziektevirus wordt overgebracht door bladluizen, waarvan de groene perzikluis (*Myzus persicae*) de meeste efficiënte vector is. De drie belangrijkste soorten vergelingsziektevirussen in suikerbieten zijn: Beet Yellows Virus (BYV), Beet Chlorotic Virus (BChV) en Beet Mild Yellowing Virus (BMV). De virussen kunnen worden beheerst door de bladluizen te bestrijden. Doel van deze veldproef is de effectiviteit bepalen van verschillende soorten insecticiden voor de bestrijding van groene perzikluizen. Omdat de zwarte bonenluis van nature ook voorkwam in de proef, is het effect op deze bladluissoort ook meegenomen.

Er is een proefveld aangelegd in Westmaas waarbij groene perzikluizen op 17 mei 2022 in het 8-10 bladstadium werden uitgezet. Vervolgens zijn diverse insecticiden gespoten.

Op basis van dit proefveld kunnen de volgende conclusies worden getrokken:

- een volveldstoepassing met Teppeki, IRS 770, IRS 789, IRS 810 en/of IRS 785 was effectief in de beheersing van groene perzikluizen (*Myzus persicae*);
- een volveldstoepassing met Teppeki, IRS 770 + Teppeki, IRS 789, IRS 810 en/of IRS 785 was effectief in de beheersing van vergelingsziekte;
- IRS 803 was niet effectief in de beheersing van groene perzikluizen en/of vergelingsziekte;
- een volveldstoepassing met Teppeki, IRS 810 en/of IRS 785 was effectief in de beheersing van zwarte bonenluizen (*Aphis fabae*);
- IRS 803, IRS 770 en IRS 789 waren niet effectief in de beheersing van zwarte bonenluizen;
- een rijentoepassing met Teppeki of IRS 785 resulteerde in dezelfde effectiviteit als een volveldstoepassing met deze systemische insecticiden met betrekking tot de beheersing van groene perzikluizen, zwarte bonenluizen en/of vergelingsziekte;
- een rijentoepassing reduceerde de hoeveelheid actieve stof per hectare suikerbieten met 68%;
- volveldstoepassingen met Teppeki, IRS 770 + Teppeki, IRS 789 en/of IRS 785 en rijentoepassingen met Teppeki en/of IRS 785 leidden tot een significant hogere opbrengst dan bij de onbehandelde controle.

## Summary

Virus yellows is an important disease in sugar beet. Virus yellows is caused by the viruses Beet Yellows Virus (BYV), Beet Chlorotic Virus (BChV) and Beet Mild Yellowing Virus (BMV), which can cause up to 50%, 30% and 35% yield reduction, respectively. The green peach aphid (*Myzus persicae*) is the most important vector. The spread of the virus in a sugar beet field can be controlled by controlling aphids with insecticides. Also the black bean aphid (*Aphis fabae*) can cause problems in sugar beet. This aphid has a much higher damage threshold, since damage to sugar beets is mainly caused by feeding from the leaves and it hardly transmits viruses. Because this is a dominant species in sugar beet and it was present in the field trial, it was also taken into account in this report.

Different insecticides were compared with a treatment without insecticide.

Therefore a field trial was conducted in Westmaas. In this trial, green peach aphids were inoculated in sugar beet in the 8-10 leaf stage (BBCH 18-19) at the 17<sup>th</sup> of May, 2022. Plots were sprayed with insecticides according to the protocols.

The aim was to study the efficacy of different insecticides on the control of aphids and virus yellows in sugar beet. From this trial it can be concluded that:

- broadcast applications with Teppeki, IRS 770, IRS 789, IRS 810 and IRS 785 were effective in the control of green peach aphids (*Myzus persicae*);
- broadcast applications with Teppeki, IRS 770 + Teppeki, IRS 789, IRS 810 and IRS 785 were effective in the control of BMV;
- IRS 803 was not effective in the control of green peach aphids and/or virus yellows;
- a broadcast application with Teppeki, IRS 810 and IRS 785 was effective in the control of black bean aphids (*Aphis fabae*);
- IRS 803, IRS 770 and IRS 789 were not effective in the control of black bean aphids;
- a band application with Teppeki or IRS 785 had the same efficacy as a broadcast application in the control of green peach aphids, black bean aphids and/or virus yellows;
- band applications reduced the amount of insecticide per hectare with 68%.
- broadcast applications with Teppeki, IRS 770 + Teppeki, IRS 789 or IRS 785 and band applications with Teppeki or IRS 785 resulted in a higher yield compared to the untreated control.

## 1. Introduction

Virus yellows is an important disease in sugar beet. Virus yellows is caused by the viruses Beet Yellows Virus (BYV), Beet Chlorotic Virus (BChV) and Beet Mild Yellowing Virus (BMV), which can cause up to 50%, 30% and 35% yield reduction, respectively. The green peach aphid (*Myzus persicae*) is the most important vector. The spread of the virus in a sugar beet field can be controlled by controlling aphids with insecticides. Since virus yellows occurs in spots in the field, it is recommended to artificially inoculate field trials with *Myzus persicae* infected with one of the viruses to achieve a homogeneous distribution of virus in field trials. The black bean aphid (*Aphis fabae*) can also cause damage in sugar beet. This aphid has a much higher damage threshold compared to the green peach aphid, since damage to sugar beets is mainly caused by feeding from the leaves and it hardly transmits viruses. Because this is an important species in sugar beet, it is also taken into account in this research. Since 2019, several field trials were conducted to test the efficacy of new insecticides and/or new spraying techniques against aphids and virus yellows. This is necessary for farmers to have enough active ingredients to control aphids and virus yellows in the future and to achieve the goals of the Farm-to-Fork strategy of the European Commission, in which it is mentioned that farmers have to reduce the amount of pesticides in 2030 compared to the reference years 2015-2017. It is important to have different active ingredients available for farmers to prevent the development of insecticide resistant aphids. It has already been reported that *Myzus persicae* can be resistant against different insecticides, like pyrethroids and pirimicarb (Bass et al., 2014).

This field trial was conducted under Good Experimental Practises (GEP, Annex A).

## **2. Materials and methods**

### **2.1 Trial site**

The field trial was located in a sugar beet field in Westmaas, the Netherlands (Annex B).

### **2.2 List of products**

Table 1 gives an overview of the treatments used in this study. Sugar beet seeds of the variety Leontina KWS were treated and delivered by KWS (Einbeck, Germany). All seeds, including the untreated control, were treated with the fungicide Tachigaren (14.7 g hymexazol per 100.000 seeds) and the insecticide Force (10 g tefluthrin per 100.000 seeds) to prevent influences of fungi and soil pests on plant establishment. Tefluthrin does not have any effect on green peach or black bean aphids (Wauters & Dewar, 1995). A homogeneous plant establishment in this trial is necessary, since the spread of virus yellows is influenced by plant spacing (Heathcote, 1974).

### **2.3 Drilling**

Drilling was done with a precision sowing machine (Monosem Mecca 2017) adapted for sowing of field trials. Sowing distance within the rows was 18.0 cm and 50 cm between rows. The field trial was sown on the 16<sup>th</sup> of March, 2022. The trial was designed as randomised blocks in four replications (Annex C). Gross plot size: 3 meters wide (6 rows) and 16 meters long. Nett plot size: 3 meters wide (6 rows) and 12 meters long. General field data can be found in Annex D.

### **2.4 Inoculation with aphids**

To obtain a homogenous distribution of green peach aphids and BMV, the trial was inoculated with reared green peach aphids infected with BMV in BBCH18-19 on the 17<sup>th</sup> of May, 2022 (treatments 1, 3-10).

In 2021, sugar beets containing Beet Mild Yellowing virus (BMV) were collected from a sugar beet field in Klaaswaal (Netherlands; IRS diagnostic sample 21-260-1). These sugar beets were potted in a sand-potting soil mixture with a ratio of 1:1 and were placed in the climate chambers at IRS (Dinteloord). Climate room conditions were 23°C for 16 hours under LED lights and at 16°C for 8 hours in the dark each day. Green peach aphids (*Myzus persicae*), originally obtained from the Laboratory of Entomology of Wageningen University and Research (NL) in 2018, were transferred from virus free sugar beets to the leaves of the infected sugar beets. After 48 hours, the aphids were collected and transferred to six week old sugar beet plants (grown in 700 ml pots; variety Kleist, Strube GmbH, Söllingen, Germany) in the climate chambers and placed in an aphid rearing cage. Every three to four weeks, leaves with aphids were cut off and transferred to new, six weeks old plants to maintain the culture of BMV containing green peach aphids in the climate chambers.

For field inoculation, leaves with aphids from the plants with BMV in aphid rearing cages in the climate chambers were cut off and carefully transported to the field trials in small boxes. Three plants in row 2 and three plants in row 5 of each plot were marked with yellow sticks and inoculated with ten aphids per plant, by transferring the aphids using a small paint brush. Plant numbers 10, 20 and 30, counting from the beginning of row 2 and from the end of row 5, were inoculated. All plots were inoculated, except plots of treatment 2 (non-inoculated control).

One day before inoculation (16<sup>th</sup> of May, 2022), the commercial field (except for the field trial) was sprayed with Teppeki (0.14 kg/ha) to prevent spread of aphids over the field.

## 2.5 Application of treatments

Treatment 1 was the inoculated, untreated control. Treatments 2 to 10 were sprayed according to the schedule in table 1. Insecticides in treatments 2 to 8 were applied with a broadcast application, where the entire area of each plot was sprayed. Applications of these treatments were conducted by Wageningen Plant Research (WPR; location Westmaas), using a CHD field trial sprayer (system Van der Wey, with Lechler Nozzle 120-02 at 3.0 bar, at 2.3 km/h and 400 liter spraying solution per hectare) to apply the different treatments (Annex D). These nozzles had a 75% drift reduction at the pressure used (TCT, 2019). Applications of treatments 9 and 10 were conducted by IRS, using an row sprayer (6 rows width, with Nozzle 6503 E, at 3.6 km/h and 300 liters spraying solution per hectare). With the band sprayer the dosage was kept the same as with the broadcast sprayer, but only 16 centimeters out of 50 centimeters row width was sprayed (32%), resulting in a 68% reduction in active ingredient per hectare of sugar beets.

## 2.6 Assessment of efficacy

The effect of various treatments on the plants and aphids was measured by assessing plant establishment, the number of aphids and other insects per plant, phytotoxicity, vigour, canopy closure and percentage of plants with virus yellows.

Final plant stand density was determined at BBCH 14 (4th of May) by counting the number of plants in the middle four rows of each plot. Plant stand density was determined by calculating the percentage of plants related to the number of seeds sown.

Efficacy of the treatments on aphids was established by counting the number of green peach aphids and naturally occurring black bean aphids per plant on various moments in time (Table 2). On the same plants, the number of other aphids and the number of beneficials (e.g. eggs, larvae and adults of ladybird beetles, soldier beetles, spiders, parasitic wasps, hoverflies, lacewings) were counted as well (data only shown in Annexes). Based on the aphid data, percentage of plants with green peach aphids, black bean aphids and total aphids were calculated (data only shown in Annex I).

**Table 2.** Overview of dates and assessed plants during aphid observations. Plants were assessed for aphids, other pests and beneficials. Plants were counted starting at the beginning of row 2 and 4 and at the end of row 3 and 5.

<i>date</i>	<i>days after aphid inoculation</i>	<i>rows counted</i>	<i>plant number counted in each row</i>	<i>leaf stage</i>
23-5-2022	6	2*, 5*	5, 10**, 15, 20**, 25, 30**	BBCH31
27-5-2022	10	2*, 5*	5, 10**, 15, 20**, 25, 30**	BBCH33
1-6-2022	15	2*, 5*	5, 10**, 15, 20**, 25, 30**	BBCH35
14-6-2022	28	2*, 5*	10**, 20**, 30**	BBCH39

\* row with inoculated plants.

\*\* inoculated plant.

Plants were scored for symptoms of phytotoxicity when they showed stunting, deformation, discoloration, necrosis or chlorosis caused by insecticide application. The percentage of plants showing phytotoxicity symptoms was assessed on the 27<sup>th</sup> of May, 29<sup>th</sup> of June and 15<sup>th</sup> of July. In addition, whole plots were scored for vigour on a scale from 1 (dead crop) to 10 (highly vigorous crop) on 2<sup>nd</sup> of June.

The number of plants showing symptoms of yellowing were counted in the middle four rows (row 2-5) of each plot on 29<sup>th</sup> of June, the 15<sup>th</sup> of July, 29<sup>th</sup> of July, 26<sup>th</sup> of August and the 20<sup>th</sup> of September. The percentage of plants with yellowing virus was calculated based on the total number of emerged plants on the 4<sup>th</sup> of May.

## **2.7 Harvest**

The field trial was harvested on 22<sup>nd</sup> of September 2022 with the six row sugar beet harvester of IRS (PASSI). From each plot the gross weight was measured and a subsample of 60-80 kg was taken to the tare house of Cosun Beet Company (Dinteloord, NL). The soil tare, sugar-, potassium-, sodium-, amino nitrogen-, and glucose content was determined. Based on quality assessments and net weight (=gross weight - soil tare), sugar percentage, sugar yield (t/ha) and financial yield (€/ha, based on 45 €/ton sugar beets with 17% sugar) were calculated. Costs of spraying and products were not taken into account.

## **2.8 Analysis of data**

Since data on number of aphids per plant did not follow a normal distribution, these data were log transformed ( $y = \log_{10}(x+1)$ ) before statistical analysis.

Data was analysed by using a one-way ANOVA using Fisher Protected LSD. Analyses were performed using Genstat Software Package 21.0.

**Table 1.** Overview of treatments in the field trial in Westmaas, 2022 (trial code: 22-11-12.05). Trial was inoculated with green peach aphids (*Myzus persicae*) on the 17<sup>th</sup> of May.

number	treatment	Treatment				
		16 May	19 May	25 May	1 June	7 June
1	untreated control	-	-	-	-	-
2	not inoculated control + Teppeki <sup>1</sup>	-	Teppeki (0.14 kg/ha)	-	-	-
3	Teppeki	-	Teppeki (0.14 kg/ha)	-	-	-
4	IRS 770 + Teppeki	-	IRS 770 (0.25 l/ha) + Actirob (1 l/ha)	-	Teppeki (0.14 kg/ha)	-
5	IRS 803	-	IRS 803 (2.5 l/ha) + Dynex (1.5 l/ha) <sup>3</sup>	IRS 803 (2.5 l/ha) + Dynex (1.5 l/ha)	IRS 803 (2.5 l/ha) + Dynex (1.5 l/ha)	IRS 803 (2.5 l/ha) + Dynex (1.5 l/ha)
6	IRS 789	IRS 789 (0.75 l/ha) + Actirob (2 l/ha)	-	-	IRS 789 (0.75 l/ha) + Actirob (2 l/ha)	-
7	IRS 810	-	IRS 810 (0.2 l/ha)	-	-	-
8	IRS 785	-	IRS 785 (0.25 kg/ha)	-	-	-
9	IRS 785 (band application) <sup>2</sup>	-	IRS 785 (0.080 kg/ha) <sup>2</sup>	-	-	-
10	Teppeki (band application) <sup>2</sup>	-	Teppeki (0.045 kg/ha) <sup>2</sup>	-	-	-

<sup>1</sup> This treatment was sprayed with Teppeki (0.14 kg/ha) to prevent damage by naturally occurring green peach aphids.

<sup>2</sup> This treatment was sprayed with a row sprayer (16 cm of the row was sprayed instead of 50 cm). The concentration of the treatment was kept similar as in treatment 3 and 8, which means that only 32% of the dosage was used compared to a full field application.

<sup>3</sup> Due to heavy rain on the 19<sup>th</sup> of May just after application, this treatment was repeated on the 20<sup>th</sup> of May, because this was a contact insecticide. All other insecticides were systemic insecticides.

### 3. Results and discussion

#### 3.1 Effect on phytotoxicity and vigour

No symptoms of phytotoxicity were observed in any of the treatments at any assessment date (Table 3; Annex F) and also, no significant effect on vigour at canopy closure was observed between treatments (Table 4; Annex F).

**Table 3.** Number of plants showing symptoms of phytotoxicity.

<i>treatment</i>	<i>phytotox</i>		
	27 May	29 June	15 July
1 untreated control	0	0	0
2 not inoculated control + Teppeki	0	0	0
3 Teppeki	0	0	0
4 IRS 770 + Teppeki	0	0	0
5 IRS 803	0	0	0
6 IRS 789	0	0	0
7 IRS 810	0	0	0
8 IRS 785	0	0	0
9 IRS 785 (band application)	0	0	0
10 Teppeki (band application)	0	0	0

8 IRS 785	7.5
9 IRS 785 (band application)	7.0
10 Teppeki (band application)	7.5
P	0.269
LSD 5% significance	- not significant

### 3.2 Effect on aphids

On the 23<sup>rd</sup> of May, plants of all treatments had significantly less green peach aphids compared to the plants of the untreated control, except for plants of treatment IRS 770 and IRS 803 (Table 5; Annexes E and I). IRS 803 had significantly more green peach aphids than the untreated control.

On the 27<sup>th</sup> of May, 1<sup>st</sup> of June and 14<sup>th</sup> of June, plants in plots of all treatments, except IRS 803 (treatment 5), had significantly less green peach aphids compared to the untreated control. Treatments 2, 4, 6, 7, 8, 9 and 10 did not differ significantly from the control treatment with Teppeki (treatment 3).

The treatments with a band application (treatment 9 and 10), in which only 32% of the ground surface were sprayed, were not significantly different in the number of green aphids per plant from treatments 3 (Teppeki) and 8 (IRS 785). This means that the amount of the insecticides per hectare can be reduced by band spraying on small plants without any reduction of the efficacy of these systemic products to control green peach aphids.

**Table 5.** Average number of green peach aphids (*Myzus persicae*) per plant on the 23<sup>rd</sup> and 27<sup>th</sup> of May and 1<sup>st</sup> and 14<sup>th</sup> of June. Plants were inoculated with green peach aphids on the 17<sup>th</sup> of May (Westmaas, 2022). Different letters indicate significant differences within a column.

treatment	mean number of green peach aphids per plant			
	23 May	27 May	1 June	14 June
1 untreated control	2.3 b	10.6 a	7.4 a	9.4 a
2 not inoculated control + Teppeki	0.6 d	0.6 cd	1.5 bcd	2.1 b
3 Teppeki	0.8 cd	1.1 bcd	1.4 bcde	1.0 bcd
4 IRS 770 + Teppeki	2.2 bc	3.1 b	3.5 bc	0.0 d
5 IRS 803	5.2 a	10.6 a	12.4 a	6.3 a
6 IRS 789	0.2 d	0.6 cd	1.3 bcde	2.1 bc
7 IRS 810	0.6 d	1.6 bc	2.3 b	2.4 b
8 IRS 785	0.4 d	0.7 cd	1.0 cde	1.8 bc
9 IRS 785 (band application)	0.1 d	0.1 d	0.5 de	1.0 bcd
10 Teppeki (band application)	0.3 d	0.1 d	0.4 e	0.5 cd
P	<0.001	<0.001	<0.001	<0.001
significance	very significant	very significant	very significant	very significant

<sup>1</sup> Data is log transformed for statistical analysis, therefore LSD-value is not available.

On the 23<sup>rd</sup> of May, plants of all treatments had significantly less black bean aphids compared to the untreated control, except for treatment 2, 4, 5 and 6 (Table 6; Annexes E and I). Treatments 2, 7, 8, 9 and 10 were not significantly different in number of black bean aphids per plant from the treatment with Teppeki (treatment 3).

On the 27<sup>th</sup> of May and 1<sup>st</sup> of June, all treatments had significantly less black bean aphids per plant compared to the untreated control, except for treatment 4, 5 and 6. Treatments 2, 6, 7, 8, 9 and 10 were not significantly different from the treatment with Teppeki (treatment 3).

On the 14<sup>th</sup> of June, treatment 4 had significantly less aphids compared to the untreated control. This is an effect of the treatment with Teppeki on the 1<sup>st</sup> of June in this treatment. Although treatment 9 (band application with IRS 785) did not differ significantly from the

untreated control anymore, it was also not significantly different from treatment 8 (broadcast application with IRS 785).

The treatments with a band application (treatment 9 and 10), in which only 32% of the ground surface was sprayed, were not significantly different from treatments 3 (Teppeki) and 8 (IRS 785) in the number of black bean aphids per plant. This means that the total amount of insecticides per hectare can be reduced by band spraying on small plants without any reduction of the efficacy of these systemic products to control black bean aphids.

**Table 6.** Average number of natural occurring black bean aphids (*Aphis fabae*) per plant 4 days (23 May), 8 days (27 May), 13 days (1 June) and 26 days (14 June; 13 days after T2) after T1 (Westmaas, 2022). Different letters indicate significant differences within a column.

significance	significant		significant		significant		significant	

<sup>1</sup> Data is log transformed for statistical analysis, therefore LSD-value is not available.

### 3.3 Effect on virus yellows

At the 29<sup>th</sup> of June, six weeks after inoculation with green peach aphids, the first assessments was done on the percentage of plants with virus yellows per plot (Table 7; Annex G). Treatments 2, 4, 6, 8, 9 and 10 had significantly a lower percentage of plants with virus yellows compared the untreated control. Treatment 3 (control treatment with Teppeki) was at that time not significantly different from the untreated control yet.

At the 15<sup>th</sup> of July, 29<sup>th</sup> of July and 26<sup>th</sup> of August all treatments, except for treatment 5 (IRS 803) had significantly a lower percentage of plants with virus yellows compared to the untreated control.

At the 26<sup>th</sup> of August the not inoculated control had significantly the lowest percentage of plants with virus yellows.

Data of the assessment at the 19<sup>th</sup> of September are not shown, because magnesium deficiency was also visible at that time, making assessment on virus yellows questionable.

**Table 7.** Average percentage of plants showing yellowing symptoms in the middle four rows per plot. Different letters indicate significant differences within a column.

<i>treatment</i>	<i>percentage of plants with virus yellows</i>			
	29 June	15 July	29 July	26 August
1 untreated control	5.9 ab	43.1 a	49.2 a	68.4 a

### 3.4 Effect on yield

There was no significant effect of treatment on root yield (table 8; Annex H).

All treatments resulted in a significantly higher percentage of sugar, sugar yield and financial yield compared to the untreated control, except for treatments 5 and 7.

Treatments 3, 4, 6, 8, 9 and 10 had significantly the same financial yield as the not inoculated control, which had the highest financial yield.

**Table 8.** Average yield per treatment expressed in root weight (t/ha), sugar content (%), sugar yield (t/ha) and financial yield (€/ha). Different letters indicate significant differences within a column. The field trial was harvested on 22<sup>nd</sup> of September 2022

#### 4. Conclusions

The aim was to study the efficacy of different insecticides on the control of aphids and virus yellows in sugar beet. From this trial, with a high incidence of aphids and virus yellows in the untreated control, it can be concluded that:

- broadcast applications with Teppeki, IRS 770, IRS 789, IRS 810 and IRS 785 were effective in the control of green peach aphids (*Myzus persicae*);
- broadcast applications with Teppeki, IRS 770 + Teppeki, IRS 789, IRS 810 and IRS 785 were effective in the control of BMVY;
- IRS 803 was not effective in the control of green peach aphids and/or virus yellows;
- a broadcast application with Teppeki, IRS 810 and IRS 785 was effective in the control of black bean aphids (*Aphis fabae*);
- IRS 803, IRS 770 and IRS 789 were not effective in the control of black bean aphids;
- a band application with Teppeki or IRS 785 had the same efficacy as a broadcast application in the control of green peach aphids, black bean aphids and/or virus yellows;
- band applications reduced the amount of insecticide per hectare with 68%.
- broadcast applications with Teppeki, IRS 770 + Teppeki, IRS 789 or IRS 785 and band applications with Teppeki or IRS 785 resulted in a higher yield compared to the untreated control.

## Annex A GEP CERTIFICATE IRS

Netherlands Food and Consumer  
Product Safety Authority  
Ministry of Agriculture,  
Nature and Food Quality

### ***Certificate***

of Official Recognition of Efficacy Testing Organisations in the Netherlands  
This certifies that, in conformity with the request of December 13, 2019

#### **Stichting IRS**

Residing: Kreekweg 1, Dinteloord the Netherlands

has officially been recognised as an organisation for efficacy testing in the Netherlands.

As has been laid down in the 'Regeling gewasbeschermingsmiddelen en biociden' (Regulation Crop Protection Products and Biocides) of September 26, 2007 (Staatscourant 2007, 386).

This recognition commences on: December 19, 2020  
and expires on: December 19, 2026

The above organisation is competent to carry out efficacy trials/tests in the categories mentioned in the annex of this certificate.

Utrecht, October 27, 2020

For the Minister of Agriculture, Nature and Food Quality,

Ton van Arnhem

Director NPPO (National Plant Protection Organization)

---

## **Annex**

ORGANISATION is officially recognised as being competent to carry out efficacy trials/tests in the following categories:

- Outdoor crops of sugar beet and chichory

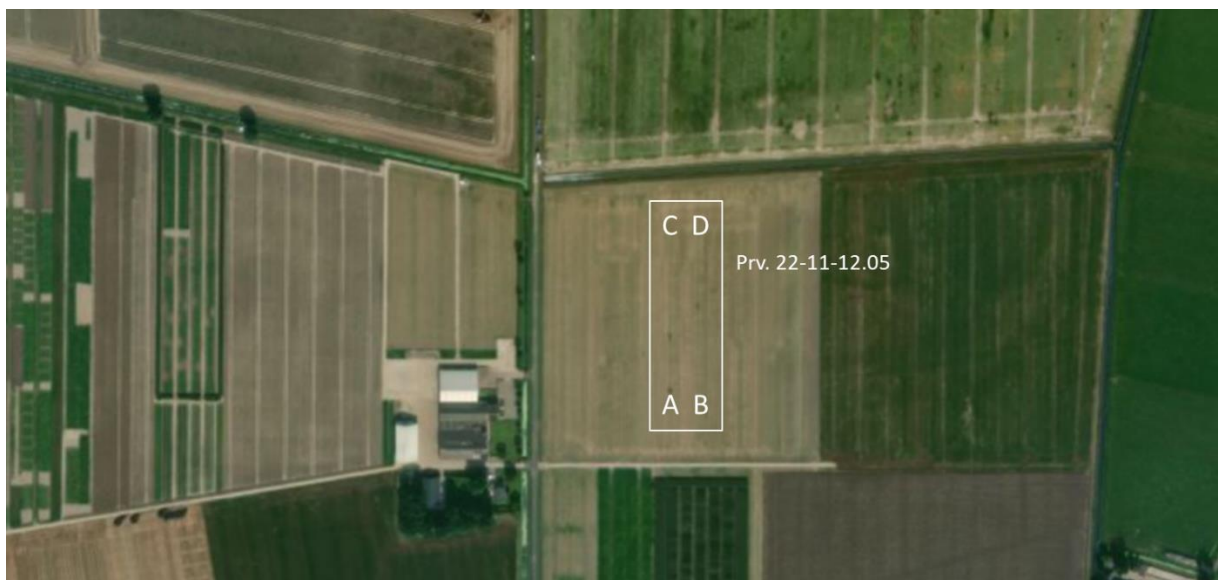

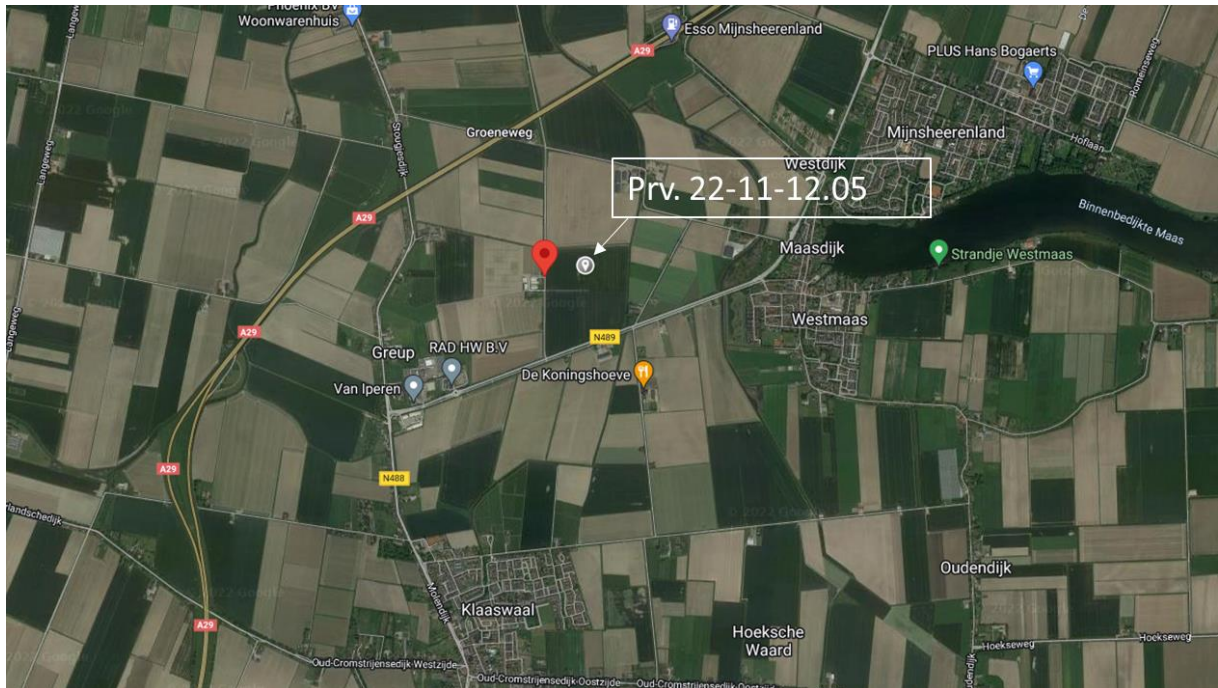

This annex has been approved by Ton van Arnhem  
*Director NPPO (National Plant Protection Organisation)*

## Annex B Location field trial

IRS trial field 22-11-12.05
